Totally Potted
Making the most of your media

Neil Mattson
Asst. Professor and Floriculture Extension Specialist
nsm47@cornell.edu

Outline

• Properties of media
  – Physical
  – Chemical
  – Biological
• pH/EC testing
• Media components
• Compost considerations
What does soil do for plants?

Supplies
- Water
- Nutrients
- Air (oxygen)

Anchors the plant in the pot
May help/hinder the plant in fighting off root diseases

container media versus field soils

<table>
<thead>
<tr>

Physical Properties of Potting Media

- **Bulk Density**: dry weight of substrate / volume
  - ↑bulk density → heavier container

- **Moisture holding capacity** = the amount of water held (% by volume at container capacity)

- **Porosity (aeration)** = the volume of air space (% by volume at container capacity)

Selecting the right substrate is a balance between:

**Moisture holding ↔ Air porosity**

- **Rule of Thumb**: choose a mix where:
  - Total porosity is greater than 50%
  - Moisture holding capacity is greater than 40%
  - Air porosity is greater than 10%

Aeration and Water Holding affected by particle size and container height

- **larger particle size**:
  - increased aeration
  - decreased water holding

- **smaller particle size**:
  - poor aeration
  - increased water holding

The particle size of most soils is too fine for use in containers
Particle size effects water holding capacity/aeration and height of the water table

Water table height is only affected by particle size, not by container height
Importance of Aeration (Air Filled Pore Space) and Plant Growth

• Oxygen is needed for normal root growth and respiration
• If normal root growth cannot occur the plant will have problems taking up water and nutrients

Symptoms of Low Aeration

• Mild-moderate stress
  – less vigorous growth
  – smaller leaves
  – dark green or chlorotic leaves
• Severe stress
  – poor root growth/shallow growth (root growth only toward top of container)
  – leaf drop
  – wilting in the early afternoon (can also be caused by high salinity/disease)
Soil Chemical Responses

- $\text{SO}_4^{2-} \rightarrow \text{H}_2\text{S}$ which is toxic to plants (this smells like rotten eggs)
- $\text{NO}_3^- \rightarrow \text{NO}_2^-$ (toxic)
- $\text{Mn}^{4+} \rightarrow \text{Mn}^{2+}$ (toxic)
- $\text{Fe}^{3+} \rightarrow \text{Fe}^{2+}$ (non toxic)

Fresh weight of chrysanthemums and air filled pore space

Chemical properties of Potting Media

- **pH**: effects plant nutrient availability →
  - optimal: 5.5 – 6.5
- **Soluble salts**
  - measured by electrical conductivity
  - optimal: 0.5-2 mS/cm
  - CRF: 0.2-0.5
- **Cation exchange capacity (CEC)**
  - ability of substrate to hold positively charged fertilizer salts
  - more is better

Iron deficiency is common at high pH

Symptoms:
yellowing between the veins on upper leaves

Correcting Iron Deficiency

Quick solution:
• Foliar application of iron chelate
  - The only way to correct severely affected tissue

Short-term:
• Drenches with iron chelate

Long-term:
• Lower substrate pH
• Check fertilizer bag for presence of iron chelates
Solubility of Various Iron Forms

Phytotoxicity and Foliar Iron Sprays

Where do salts come from?

• Water source
  – salt deposits, limestone, sea-water incursion, road salt
    Target: 0.2-0.75 dS/m
    Acceptable: 0-1.5 dS/m
### Salts in container media

- **Controlled Release Fertilizers have much lower EC readings**
Using Soluble Salts to Diagnose Nutrient Disorders

**Excess salts mean**
- fertilizer levels exceed plant requirements
- insufficient leaching during irrigation
- irrigation water contains a high amount of dissolved elements

**Low salt levels**
- insufficient fertilizer levels
- excess leaching during irrigation

Symptoms Excess Soluble Salts

**Osmotic stress**
- Wilting
Symptoms of Excess Soluble Salts

- marginal chlorosis → necrosis of older leaves

Symptoms of Excess Soluble Salts

- Death of root tips
- Increased *Pythium* root rot susceptibility
Symptoms low soluble salts

- Fertility is too low
  - plant growth stunted

Pour Thru method pH/EC monitoring

- Nondestructive
- Use on each important crop
- Sample periodically (ideally every 1-2 weeks)
- Take 5-10 samples per crop each time and average this

Source: North Carolina State University, http://www.pourthruinfo.com
Pour Thru Methods

1) Irrigate your crop one hour before testing
   • Containers should be fully saturated
   • If fertilization is periodic (ex: weekly), test on the same day of the fertilizing cycle

Pour Thru Methods

2) After container has drained for one hour, place saucer under container
Pour Thru Methods

3) Pour enough distilled water on the surface of the container media to get 50 mL (1.5 ounces) of leachate

<table>
<thead>
<tr>
<th>Container Size</th>
<th>Water to Add</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>mL</td>

</tr>
<tr>
<td>1 gallon</td>
<td>150</td>
</tr>
<tr>
<td>3 gallon</td>
<td>360</td>
</tr>
</tbody>
</table>
Pour Thru Methods

4) Collect Leachate for pH and EC testing

Pour Thru Methods

5) Calibrate pH and EC meters before testing (needs to be done every day you use the meters)
Pour Thru Methods

6) Measure pH and EC of samples

Media sampling for 1:2 dilution method or sending to lab for analysis

• take slices/cores of media from the area where roots are actively growing
• take samples from 10 representative plants
• pool the samples together
• most labs require 1-2 cups of material
• taking sample from the upper third of the container will overestimate fertility
1:2 dilution method pH/EC monitoring

- air dried media sample
- combine 1 part media and add 2 parts DI water (by volume)
- mix thoroughly
- allow it to stand for 30 minutes
- pour some of sample into a cup

EC guidelines by extraction method

<table>

</tr>
<tr>
<td>&gt;1.1</td>
<td>&gt;2.25</td>
<td>&gt;6.0</td>
<td>&gt;7.8</td>
<td>Extreme. Most crops will suffer salt injury at these levels. Immediate leaching required.</td>
</tr>
</tbody>
</table>

\(^1\)Adapted from: On-site testing of growing media and irrigation water. 1996. British Columbia Ministry of Agriculture.
\(^2\)Due to the variability of the PourThru technique results, growers should always compare their results to the SME method to establish acceptable ranges.
Saturated Media Extract

- the most universal method for laboratory testing of container media (not practical for “in-house” measurements)
- DI water is slowly added and stirred to the media sample (≈1 cup media) until a “glistening paste” is formed
- The mixture is allowed to stand for 30-90 minutes
- The filtrate is extracted under suction
- Filtrate analyzed for pH/nutrients of interest etc.

EC: conversions and confusions

<table>
<thead>
<tr>
<th>Method</th>
<th>Abbreviation</th>
<th>Units</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>millisiemens</td>
<td>mS/cm</td>
<td>EC x 10⁻³/cm</td>
<td>2.25 mS/cm</td>
</tr>
<tr>
<td>millimhos</td>
<td>mmhos/cm</td>
<td>EC x 10⁻⁷/cm</td>
<td>2.25 mmhos/cm</td>
</tr>
</tbody>
</table>

A new term for millimhos is millisiemens, which is the metric (SI) unit of expressing electrical conductance. There is no change in value, just terminology.

deci/siemens | dS/m         | EC x 10⁻³/m | 2.25 dS/m  |

Decisiemens per meter is the common term used in scientific literature of expressing electrical conductance. The term deci- means one-tenth and the term milli- means one-thousandth, so a deci- is 100 times greater than a milli-. While expressing dS/m, the denominator is given in terms per meter (m) and for mS/cm the denominator is given in terms per centimeter (cm). One meter contains 100 cm, therefore when comparing values in dS/m and mS/cm, the zeros cancel out mathematically and the decimal point appears at the same place for both units (i.e., 2.25 dS/m = 2.25 mS/cm).

<table>
<thead>
<tr>
<th>umho x 10⁻³/cm</th>
<th>EC x 10⁻³/cm</th>
<th>225 umho x 10⁻³/cm</th>
</tr>
</thead>
</table>

Some labs prefer to express EC as a whole number (i.e., 225), therefore the decimal point is shifted two places to the right. (The NSUC Plant Disease and Insect Clinic reports in these units.)

<table>
<thead>
<tr>
<th>micromhos</th>
<th>µmhos/cm</th>
<th>EC x 10⁻⁶/cm</th>
<th>2250 µmhos x 10⁻⁶/cm</th>
</tr>
</thead>
</table>

The term micro- means one-millionth and is 1000 times smaller than a milli-.
Biological Properties

- Organically based substrates (peat, compost, bark, soil) may contain several living organisms
- Fungi, microbes, water-molds
  - many of these will be neutral (do not harm plant/roots)
  - some are beneficial, such as mycorhizae that retain nutrients
  - some are harmful: root-rots
- Insects - especially fungus gnats
- Weed seeds

Examples of biologicals added to substrates

- Pro-Mix products contain Mycorise® Pro – mycorrhizae help retain nutrients, and help roots scavenge water/nutrients
- Some Pro-Mix products contain Subtilex® biofungicide. This is a bacteria (Bacillus subtilis) that helps prevent root pathogens, such as damping, off from gaining-hold
- RootShield® WP – the substrate can be drenched with this, contains a fungus, Trichoderma, which helps protect roots from pathogens
  - Also RootShield granules (last 12 weeks)
Thoughts on Media Components

Organic media components

- Sphagnum peat moss
- Coconut coir
- Pine and hardwood bark
- Rice hulls
- Leaf and yard waste composts
- Animal waste composts
Sphagnum peat

- high moisture holding
- low pH (limestone needed to raise)
- High CEC
- Renewable?

Not all peat is created equal...

- Virgin peat (top layers), longer fibers less decomposed
  - Has better drainage (aeration)
  - Can be used in lower perlite and perlite free mixes
- Lower layers, peat is finer/more decomposed
  - Propagation mixes, consumer mixes, mushroom compost
  - Higher cation exchange capacity
  - Mixes hold more water, less aerated
  - Need more perlite to get enough aeration
Coconut coir

- Shredded coconut husk

- High moisture holding
- Moderate pH (5.5-7.0)
- Little nutrients
- High salts (leach before use?)
- Renewable!

Coir breaks down over time

3 years old  Fresh
Pine and hardwood bark

- partially decomposed/composted is best
  - When used fresh can decompose rapidly
  - Microorganisms compete with plants for soluble nitrogen (this is called “nitrogen draft” – a rapid depletion of media nitrogen)
  - Composting takes time and space so some growers do not do this, need to add nitrogen
- maintains porosity for a long period of time
- cheap – often used in the nursery industry because of the large containers used
- overtime media pH may decrease

Nitrogen Draft

<table>
<thead>
<tr>
<th>Large N draft</th>
<th>Intermediate N draft</th>
<th>Low N draft</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardwoods</td>
<td>Pine sawdust</td>
<td>Peat</td>
</tr>
<tr>
<td>Ponderosa pine bark</td>
<td>Douglas fir bark</td>
<td>Redwood bark</td>
</tr>
<tr>
<td>Jeffrey pine bark</td>
<td>Red fir bark</td>
<td>Sugar pine bark</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Incense cedar bark</td>
</tr>
</tbody>
</table>

If using fresh wood products, to account for N draft
- Add 4 pounds nitrogen per cu. yard for large N draft
- 2 pounds nitrogen for intermediate draft materials
• Historically pine bark 3/8-1/2 inch size has been preferred
• Whole tree (WT) is a new development
  – Composed of the entire aboveground parts of a pine tree including wood, bark, needles, and branches
  – Chipped and then ground with a hammer mill and screened to the desired size
  – Aging for 90 days has improved plant performance
Rice Hulls

• Current product primarily used is parboiled rice hulls (PBH) which removes rice grain and kills weed seeds, previously:
  – Aged hulls
  – Composted hulls
• Provides root-zone aeration, used as a substitute for perlite or other coarse components
• Often used 20-25% by volume
• At this incorporation rate does not affect nutrient tie up

COMPOSTS

Leaf and yard waste composts
Animal waste composts

• Decomposed, aged organic matter
• Be sure to consider:
  – Maturity
  – Particle size – if too fine – substrate will be water logged
  – Salts (can be high in manure-based composts – may need to limit to 5-10% by volume)
  – pH (often about 7.0 for finished compost)
  – Consistent/uniform source of material?
  – Quality control and testing?
Benefits of using compost

Microbes/Biologicals are one of composts benefits
  – Microbes are also sensitive to high salts (from compost or fertilizer)

Compost increases the Cation Exchange Capacity (CEC)
  – typically 100-300 meq/100 g
  – Sandy loams, typically are 0-8 meq/100 g

Porosity
  – Increases porosity in soil
  – BUT, by itself, holds too much water in a container

Peat vs. Compost
  – peat: nonrenewable/finite, “dead”
  – compost: sustainable, “alive”

Problems with “immature”/”unfinished” compost

• physical and chemical properties vary based on source and how mature
• high salts (ex: manure-based)

Unfinished/Immature compost:
• volatile organic compounds
• odor
• reheating can occur (if compost is dry and rewetted)
• may contain pathogens, weed seeds
• Media in container can rapidly settle
Other things to consider when using compost

• Tests for Maturity:
  – Quick
    • Check for odors – Ammonia, Sulfur
    • large non-composted particles
    • Temperature – young compost will still be hot!
  – Bag test:
    • Moist sample in ziploc bag overnight –
      Does bag inflate? Off odors?

Commercial tests
Solvita®: test kit for ammonia and CO₂ – the principle emissions in immature composts
  – About $15 / test
Commercial testing labs

Cornell Nutrient Analysis Lab
  – $45: % organic matter, salts, N, C, C:N
  – $75: above + full nutrients

University of Maine, Soil testing lab
  – $45: bulk density, salts, TS, TVS, C:N, most nutrients
  – $10: compost stability

Rutgers
  – $45: salts, nitrate-N, maturity index
  – $125: above + OM, C-N, moisture, coarse/inert fragments

</tbody>
</table>

Perlite

- Volcanic rock crushed and heated to 1800 F
- High aeration (depends on particle size)
- Negligible pH/CEC
- Lightweight – low bulk density
vermiculite

- Mica crushed and heated to 1400 F
- High water holding (depends on particle size)
- pH 6.0-8.9
- High CEC
- Lightweight – low bulk density
Blending components for nursery container media

• Combine various components so that media has the correct balance of physical, chemical, (and biological) properties

Example

• 80% pine bark, 10% peat and 10% sand.
  – Shredded bark has good air porosity
  – Peat increases the water-holding capacity and nutrient holding CEC
  – Sand increases the weight reducing container tip-over
What about starter nutrient charge, nitrogen draft, and pH?

Recipe for “new” UC Mix

- 0.42 cubic yards Fir bark
- 0.33 cubic yards Peat
- 0.25 cubic yards Sand
- 1 pound Potassium-nitrate (13-0-46)
- 2 pounds Single superphosphate (0-20-0)
- 5 pounds Pulverized dolomitic limestone
- 1 pound Ferrous-sulfate

QUESTIONS?

Neil Mattson
